#### **ABSTRACT**

The Kirishi Petroleum Refinery is one of the newer refineries being built in the Soviet Union utilizing the latest standardized design which was reportedly accepted for use in 1959. This refinery has been under construction since late 1961 or early 1962 and appeared to be at least partially in production in 1967. The primary distillation facilities now in place indicate that the refinery will have an approximate annual crude oil charge capacity of six million metric tons. The number and diversity of processing units presently in place or under construction indicate that the plant will have the capability of producing a full line of fuels, tubes, waxes, and asphaltic materials.

#### INTRODUCTION

The Kirishi Petroleum Refinery is located on the east bank of the Volkhov River approximately 2 nautical miles northeast of the center of the Kirishi town complex. Upon completion, the fenced refinery area will measure approximately 3,100 by 5,400 feet and will include about 380 acres.

The Kirishi refinery was constructed to process crude oil from the Volga-Ural Region, Tatar ASSR, which now accounts for a large percentage of the Soviet Union's crude oil production. A large-diameter pipeline from the Volga-Ural Region to Leningrad via Kirishi will probably be used to transport the crude oil into the refinery. 1,2/ Relatively high sulfur and salt content of much of the Volga-Ural crude oil could present special design and maintenance problems at this refinery and could explain the construction of some of the secondary or auxiliary refinery units seen at Kirishi. 1/

Rail service into the refinery is provided by a spur from the main line between Leningrad and Vesyegonsk via Kirishi. The small scale of the available photography precluded any rail traffic counts in the refinery.

#### BASIC DESCRIPTION

## Status and Activity

A generalized description of the construction history of the refinery and associated facilities will be given. Mention of specific items will be made to point out salient points in the development of the complex.

June 1962 -- All areas in the complex had been surveyed and cleared. Small construction sites were randomly scattered throughout the cleared areas. Railroad right-of-ways were cleared into the refinery area, but due to the small scale of photography it could not be determined if tracks had been laid. The major portion of the workers' housing was completed.

June 1963 -- Construction continued throughout the complex at a moderate rate with the most noticeable progress being made in the concrete batch plant. Construction of the main primary distillation columns and the products storage tank farm had been started. The water treatment plant and additional rail spurs were under construction.

October 1964 -- Construction activity was greatly increased in the refinery area. The primary distillation columns were complete, and the associated equipment such as furnaces, heat exchangers, cooling towers, and compressor facilities were in various stages of construction. Work was in an early stage on the crude oil storage tanks, interior roads, pipelines and steamlines. The concrete batch plant was essentially complete. Earth moving work had just been started on the large water storage reservoirs located a short distance northeast of the refinery area.
